Re: National Highway Filter Media Project
Permit #WCP 080002

Dear Mr. Patel:

On 7 August 2008, the MPWC received the approved permit referenced above. The media at the treatment plant has since been changed to Greensand Plus. The filters were tested and made operational at the end of February 2009. MPWC received approval to permanently run the filters at 9.0 gpm/sq. ft. and continue with the long term pilot study at 12.0 gpm/sq. ft. in your 23 April correspondence. The results and conclusions are summarized below.

Plant setup

The National Highway Plant pumps water from the Potomac-Raritan-Magothy (PRM) formation using two groundwater production wells. Each well is capable of supplying 1,000 gallons per minute to the treatment system. Raw groundwater from the production wells is pumped to one of two vertical air stripping towers for the removal of any volatile organic contaminants. From the air stripper towers, water flows by gravity to two clear wells where lime is added for pH control. The level of the clear well basin is maintained at a near constant elevation by the operation of the level controlled high service pumps. The site utilizes two 75 HP pumps. These pumps direct water to a sodium hypochlorite contact tank and then through two GreenSand Plus media filters.

The changes made to the treatment plant eliminated the sodium bisulfite feed and the carbon dioxide feed. The media in the filter units was changed from [REDACTED] to Greensand Plus. Less sodium hypochlorite is required to disinfect the finished water and maintain an acceptable residual.

Testing Results

The current flowrates and testing period has been taking place for over three months. The iron and manganese were readily reduced to concentrations well below the respective MCL of 0.3 mg/L and 0.05 mg/L throughout the testing period. The end of the filter runs were based on time. Each unit was run for 24 hours and then backflushed for 6 minutes. The filters were alternated to run at a flowrate of 1,000 gallons per minute (gpm) or 12.0 gpm / sq. ft. just at the same flowrate the filters were run at when the

media was used to filter the water. This allowed a total flow of 1,440,000 gallons to be treated prior to the unit backwashing. There was no noticeable pressure increase throughout the filter runs.

As can be seen from the testing data included in **Appendix A**, the filters are equally removing iron and manganese at their respective flowrates.

The results from this period were compared to the initial results when the filters were run at 3.0 gpm / sq. ft and 6.0 gpm / sq. ft. There were no noticeable differences between the effluent quality when the filters were run at the lower flowrates versus the 12.0 gpm / sq. ft.

May

The influent iron concentrations to both filters ranged from 0.3 to 0.4 parts per million (ppm). The iron was completely removed during May. The influent manganese concentrations ranged from 0.215 to 0.312 ppm. The highest effluent reading taken was 0.013 ppm. As can be seen from the data included in **Appendix A** and compared to the results from the 1 July 2009 pilot test report, the effluent manganese concentrations are almost identical at both flowrates and in many cases, the concentrations are lower at the higher flowrates. The highest effluent reading was 0.013 ppm compared to 0.015 ppm at the lower flowrates. These values are well below the MCL of 0.05 ppm.

June

The influent iron concentrations to both filters ranged from 0.2 to 0.4 parts per million (ppm). The iron was completely removed during June. The influent manganese concentrations ranged from 0.235 to 0.314 ppm. The highest effluent reading taken was 0.012 ppm. As can be seen from the data included in **Appendix A** and compared to the results from the 1 July 2009 pilot test report, the effluent manganese concentrations are almost identical at both flowrates and in many cases, the concentrations are lower at the higher flowrates. The highest effluent reading was 0.012 ppm compared to 0.015 ppm at the lower flowrates. These values are well below the MCL of 0.05 ppm.

July

The influent iron concentrations to both filters ranged from 0.2 to 0.5 parts per million (ppm). The iron was completely removed during July. The influent manganese concentrations ranged from 0.214 to 0.321 ppm. The highest effluent reading taken was 0.013 ppm. As can be seen from the data included in **Appendix A** and compared to the results from the 1 July 2009 pilot test report, the effluent manganese concentrations are almost identical at both flowrates and in many cases, the concentrations are lower at the higher flowrates. The highest effluent reading was 0.013 ppm compared to 0.015 ppm at the lower flowrates. These values are well below the MCL of 0.05 ppm.

Conclusions

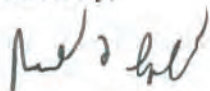

The filter units have been running for a period of over 17 months since being changed over to Greensand Plus. The removal of the media and the installation of GreenSand Plus has allowed the filter plant to eliminate both the sodium bisulfite and carbon dioxide chemical feeds. Both the necessary lime and sodium hypochlorite usage at the treatment plant have been reduced due to the media change. The plant runs have increased from 12 hour increments on the media to scheduled 24 hour runs on the new Greensand Plus.

The GreenSand Plus media does not use the sodium bisulfite or carbon dioxide necessary to run the [REDACTED] media. The elimination of these two chemicals saved the MPWC over \$41,000 per year. By pilot testing the media and increasing the flowrate, we are seeing identical or better removal efficiencies than at the lower flowrates. We also are saving backwash water. The current flowrate is four times higher than the initial test flowrate. This means that we use ¼ the amount of backwash water or save approximately 36,000 gallons of water for each cycle we run at the higher flowrate. We run over 1.4MM gallons of water prior to backwashing verses 360,000 gallons at the lower flowrate. Additionally, there is less back pressure produced against the filters and pumping equipment at the higher flowrate. Although the overall system usage is the same, there is more water available for instantaneous demand, minimizing potential system pressure changes and customer complaints.

Throughout the testing period, both filter units are removing iron and manganese to concentrations well below the respective MCL of 0.3 mg/L and 0.05 mg/L. This data matches the data obtained from the pilot test report dated 30 January 2008 when the pilot units tested the water at 12 gpm / sq. ft. At this time, MPWC respectively requests the final flowrate for the filter units to remain at 12.0 gpm / sq. ft.

Thank you for your time and attention to this matter. If you have any questions, please do not hesitate to contact me at (856) 663-0043.

Sincerely,

Richard F. Spafford, P.E.
